

Module2_lab1

September 12, 2026

Step 1: Wages with f-strings

```
[1]: name = "John"
    hourly_wage = 15.65
    hours = 35
    weekly_pay = hourly_wage * hours
    print(f"{name} worked {hours} hours and earned ${weekly_pay} this week.")
```

John worked 35 hours and earned \$547.75 this week.

Step 2: Count the warm days

```
[2]: temps = [61, 65, 72, 58, 70, 74, 68]
    high = 0
    for t in temps:
        if t > 65:
            high = high + 1
    print(high)
```

4

Step 3: Write a temperature converter

```
[3]: def F_to_C(f):
    c = (f-32)*5/9
    return round(c,1)
    F_to_C(temps[0])
```

[3]: 16.1

Step 4: A movie dictionary

```
[4]: movie = {"title": "Moneyball", "year": 2011, "rating": 7.6}
    for key, value in movie.items():
        print(key, ":", value)
```

title : Moneyball
year : 2011
rating : 7.6

Step 5: Load and inspect chickwts.csv

```
[5]: import pandas as pd
df = pd.read_csv("chickwts.csv")
df.head()
```

```
[5]:   Unnamed: 0  weight    feed
0           1     179  horsebean
1           2     160  horsebean
2           3     136  horsebean
3           4     227  horsebean
4           5     217  horsebean
```

```
[6]: df.shape
```

```
[6]: (71, 3)
```

Step 6: Interpret describe()

```
[7]: df.describe()
```

```
[7]:   Unnamed: 0  weight
count    71.000000   71.000000
mean     36.000000  261.309859
std      20.639767   78.073700
min       1.000000  108.000000
25%      18.500000  204.500000
50%      36.000000  258.000000
75%      53.500000  323.500000
max      71.000000  423.000000
```

The most interesting thing about this dataset to me is the spread of the weights. The largest chick in the dataset is nearly four times as heavy as the lightest. This is also reflected by the relatively large standard deviation of the dataset (78.1) means the coefficient of variance (stdev/mean) is roughly 30%.
